

Prof. Beatrice Mintz Jack Schultz Chair in Basic Science

Most important awards, prizes and academies

Awards: Bertner Foundation Award in Fundamental Cancer Research (1977); New York Academy of Sciences Award in Biological and Medical Sciences (1979); Papanicolaou Award for Scientific Achievement (1979); Lewis S. Rosenstiel Award in Basic Medical Research (1980); Genetics Society of America Medal (1981); Ernst Jung Gold Medal for Medicine (1990); John Scott Award for Scientific Achievement (1994); March of Dimes Prize in Developmental Biology (1996); American Cancer Society National Medal of Honor for Basic Research (1997); Pearl Meister Greengard Prize (2008); Albert Szent-Györgyi Prize for Progress in Cancer Research (2011). **Academies:** National Academy of Sciences (1973); Fellow, American Association for the Advancement of Science (1976); Honorary Fellow, American Gynecological and Obstetrical Society (1980); American Philosophical Society (1982); Fellow, American Academy of Arts and Sciences (1982); Pontifical Academy of Sciences (1986). **Degrees:** Doctor of Science, New York Medical College (1980); Medical College of Pennsylvania (1980); Northwestern University (1982); Hunter College (1986); Doctor of Humane Letters, Holy Family College (1988).

Summary of scientific research

Beatrice Mintz discovered the underlying relationship between development and cancer. She first showed that development is based on an orderly hierarchical succession of increasingly

specialized small groups of precursor or "stem" cells, expanding clonally. She proposed that cancer involves a regulatory aberration in this process, especially in the balance between proliferation and differentiation. These views were based on a series of methods of her own design, for construction and analysis of chimeric and transgenic mouse models. The models enabled the experimental study of development and of cancer within the framework of the whole organism throughout life. She produced chimeric mice (which she at first termed "allophenic") by inclusion of two genetically different cells in the early mouse embryo, thereby revealing the clonal organization. Mintz then devised modifications of chimerism to examine the roles of stem cells in cancer. Her lab. found that mouse teratocarcinoma stem cells developed normally in a normal embryo environment. This led to many new kinds of experiments in many laboratories, aimed at defining the role of a normal microenvironment on cancer cells. Her new experiments also showed that stem-like cancer cells could be grown in culture and used as "messengers" to convey specific-DNA into the organism. Later, the DNA was injected directly into the fertilized egg. Her lab. used that method to produce a mouse model of malignant melanoma resembling the human disease, so as to explore possible treatments.
